ISIS Neutron and Muon Source

More info @: www.isis.stfc.ac.uk

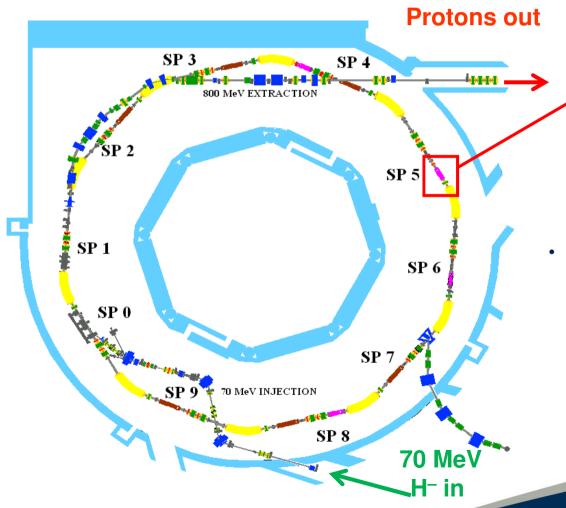

- First Beam to TS1Dec. 1984
- DHRF upgrade c.2000
- TS2 commissioned c.2009
- Now run >230µA beam current

ISIS Synchrotron HPRF

- H⁻ ions stripped to protons when injected at 70MeV
- Protons complete ~12,000 turns in next 10 ms
- Accelerated to 800MeV
- Protons extracted & transported 2 targets

• Repeats @ 50Hz 800 MeV

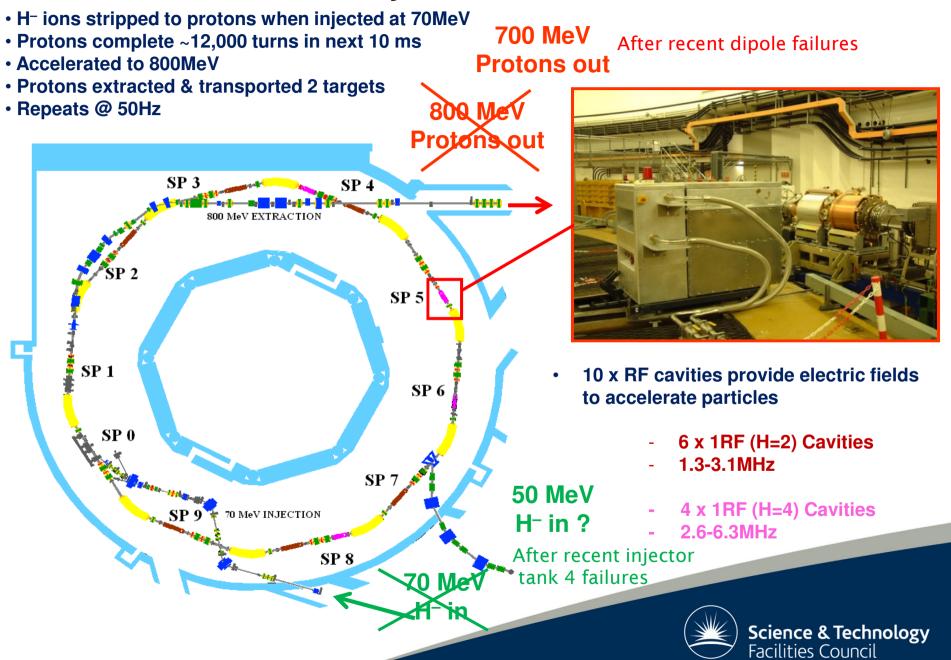

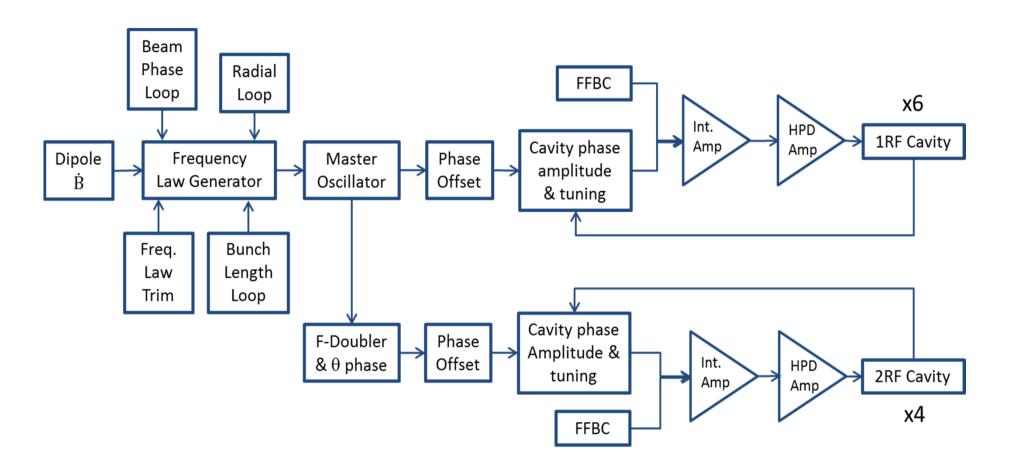

- 10 x RF cavities provide electric fields to accelerate particles
 - 6 x 1RF (H=2) Cavities
 - 1.3-3.1MHz
 - 4 x 1RF (H=4) Cavities
 - 2.6-6.3MHz

ISIS Synchrotron HPRF

LLRF: System Overview

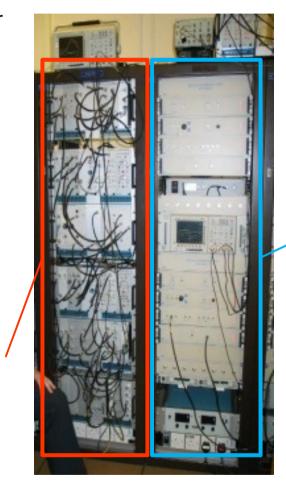

ISIS LLRF Controls (c. 2004)

Original (c. 1982)
Frequency Law Generator
/ Master Oscillator

Original 1RF Analogue LPRF controls (c.1982)

Loops to control cavity voltage amplitude and phase + tuning

2RF Analogue LPRF controls (c.1995)

Even the newer 2RF system ~10 years old.

- ageing components more likely to fail
- replacements harder to source

Time to think about replacing the system!

ISIS LLRF Upgrade – Potted History

~2005, started to consider replacements for the ageing LPRF controls:

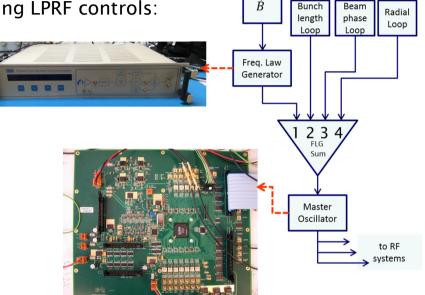

Frequency law generator:

- Lattice FPGA based
- Takes input Bdot signal and integrates to give current frequency.

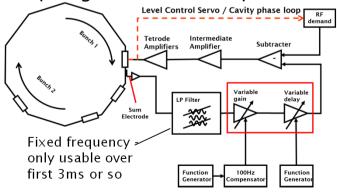

Digital Master Oscillator:

- Lattice FPGA based Voltage-to-Frequency Converter
- Provided RF signal to 10 Cavities :
 6 x 1RF, 4 x 2RF

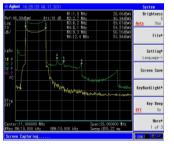

~2008 - Feed forward beam compensation

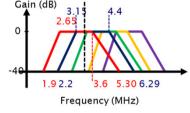

Swept digital filterbank implemented on New FlexRIO platform:

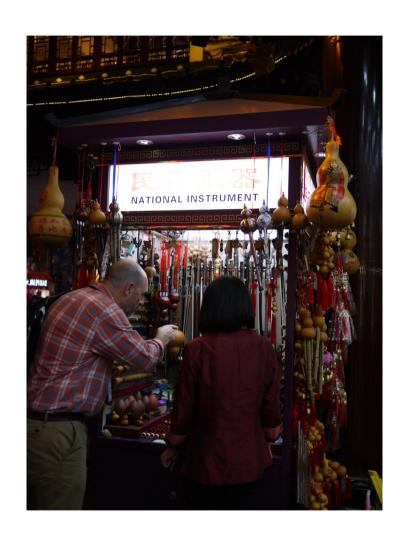

Why not use FlexRIO based system to replace LPRF controls?

NI FlexRIO - Digital LLRF

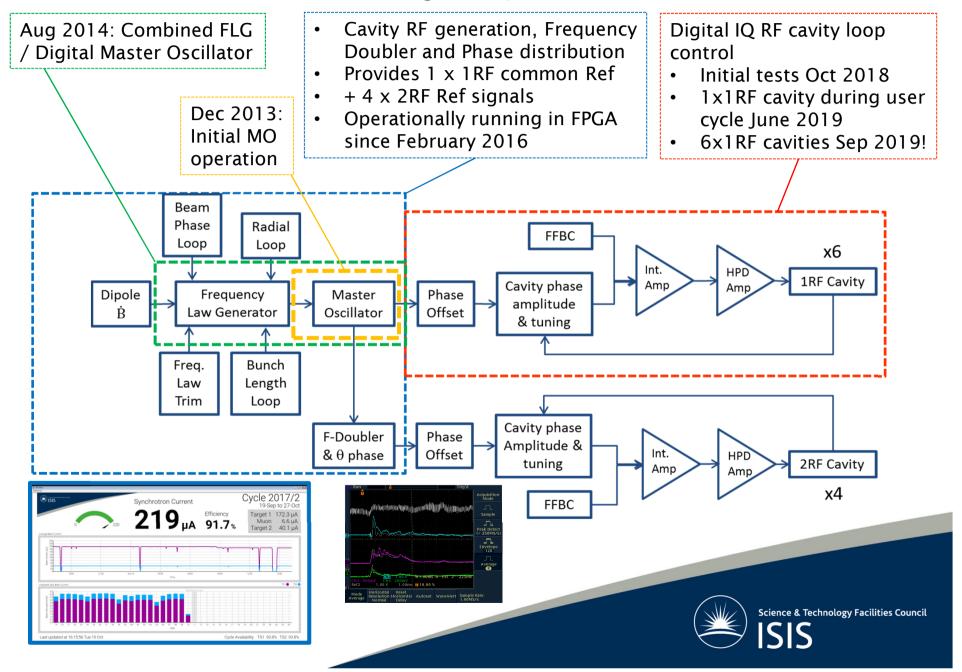

Choice of Platform

- NI global company
- Large support network
- Use of LabView FPGA for coding
 - STFC has site licence agreement
 - Many LabView users / few VHDL
- Small team / Low channel count
 - off the shelf more affordable
 - Less development time?
- Obsolescence less of a problem
 - Always an upgrade path (at a price!)

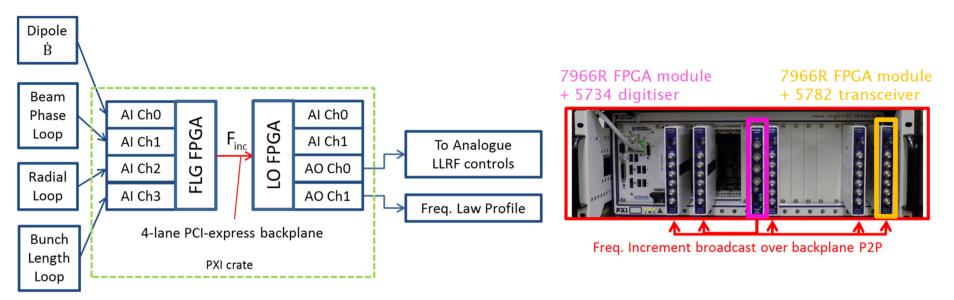

Bespoke MO -3 years / PXIe MO -6 months

D-LLRF: Staged implementation

D-LLRF - Initial system design

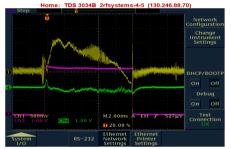

Worked well initially, for a single P2P link, but when used to close Beam Phase loop with design

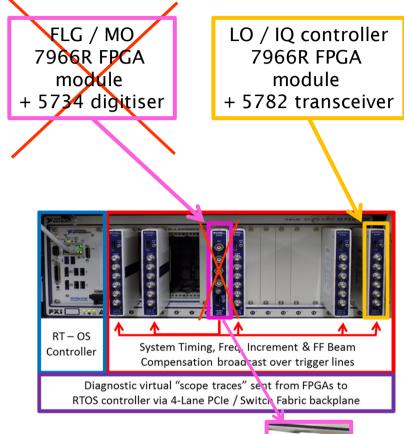

for more LOs, higher latency gave rise to catastrophic beam losses!

April 2015 code revised using PXI trigger lines for F-word broadcast rather than PCI express data stream

Other issues: loss of synchronisation over FPGA modules when running interactive mode. Cured by "Boot-up" exe RTOS deployment.

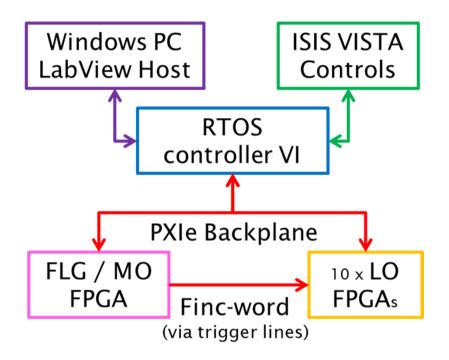

FLG / MO 7971R FPGA module + 5783 digitiser

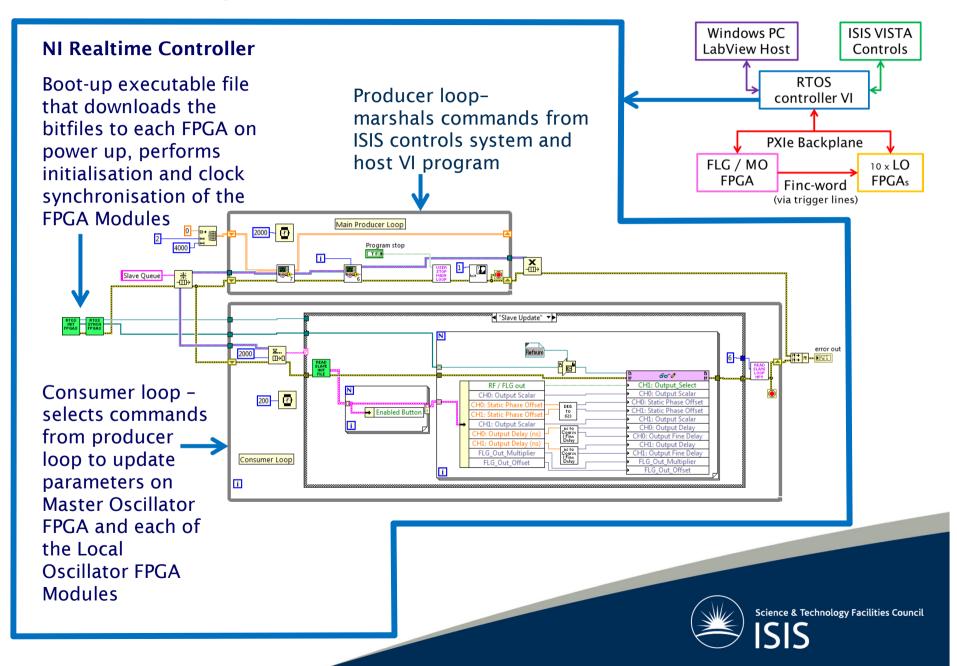

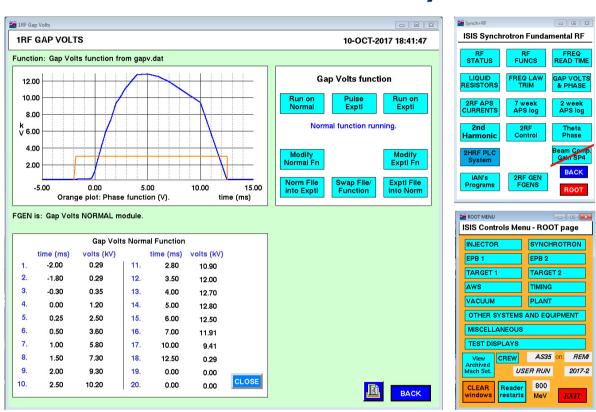

New FLG / MO Bigger FPGA!

- Faster compiles
- 4 channel transceiver to give auxiliary outputs
- FL to intensity monitor
- RF for extract timing / beam choppers etc.

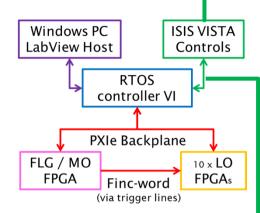

ISIS VISTA Controls system

ISIS Main Controls parameters set by machine physicists / crew

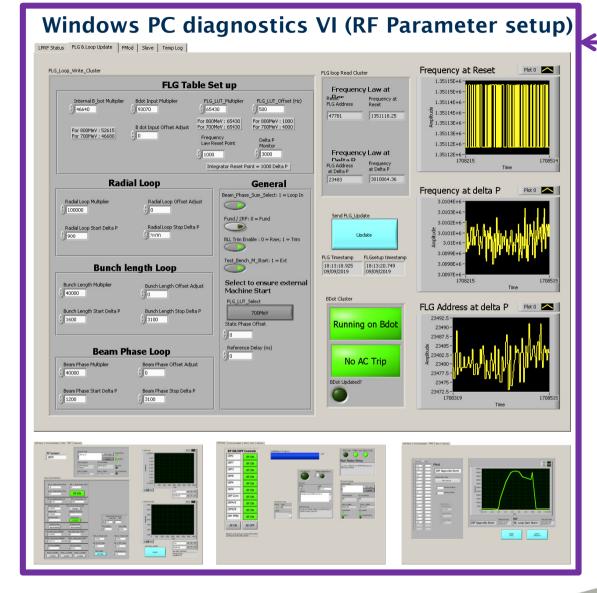

Now: PixyBroker

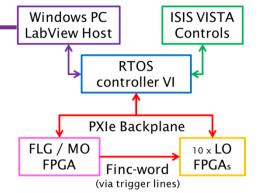

- LabView VI running on RTOS controller
- Polls Vista DB channel for changes every 2s

Soon: MQTT

- MQTT is a Client Server publish/subscribe messaging transport protocol.
- Will include experimental function pulsing etc

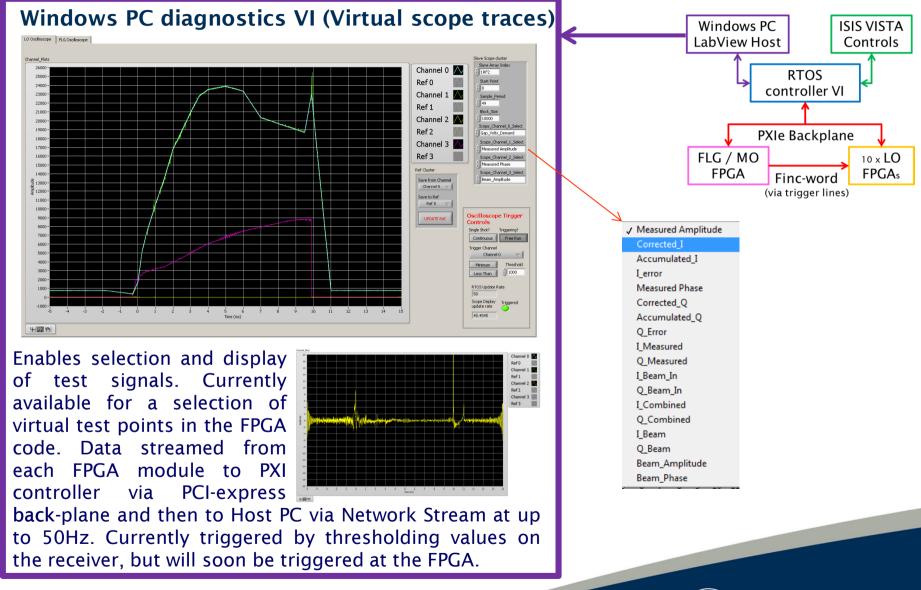

Tabbed panes allow access to parameter groups.

Now has simple LLRF On/Off buttons to replace analogue pots.

Allows interactive editing of RF setup parameters - phase offsets, Loop gains etc (set by RF team) and display of current values (eg start / stop frequency etc.)

Virtual "Function Module" channels show last sent values of VISTA controls functions.

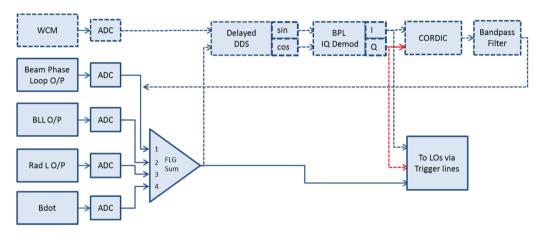

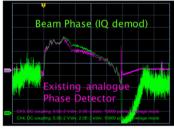

Frequency Law Generator / Master Oscillator

Implemented using LabView FPGA on NI PXIe7971R FPGA module + NI 5783 100MS/s transceiver adapter module generates the RF sweep from 1.3MHz to 3.1MHz for 1RF cavities and 2.6 to 6.3MHz for 2nd Harmonic cavities.

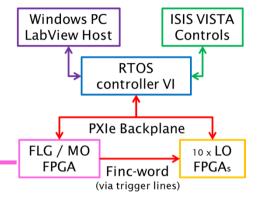

Currently using direct analogue loop inputs. Previous tests used IQ demodulation of the beam sum electrode signal followed by a CORDIC algorithm to generate a beam phase signal. This will be implemented to replace the existing

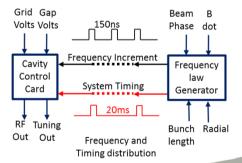

TDS 3014B - 15:41:38 04/05/2015

analogue beam phase loop with the added benefit of using the same beam signal to generate the Bunch Length Loop correction (and possibly provide Beam I and Q for FFBC).

RF Synchronisation

Backplane trigger/data lines used for system timing, frequency increment broadcast and synchronous frequency update.

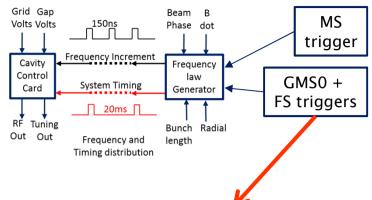

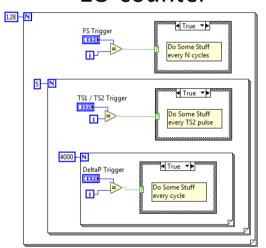

D-LLRF - ISIS Machine Timing

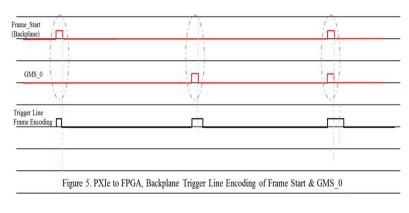

Replace MS trigger with FS trigger

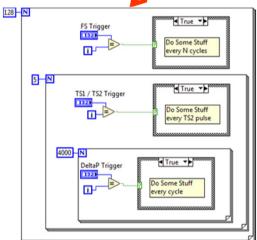

- to allow pulsing Normal / experimental Functions at MS, MS/2, MS/4....MS/640.
- Includes possibility of applying different functions for TS1 / TS2 beam pulses.

LO counter

FLG counter

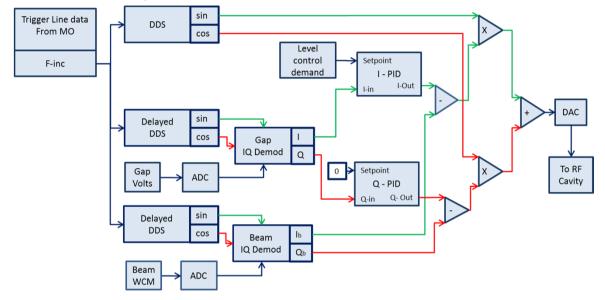

GMS 0 (or other external) triggering

to allow switch off RF for non-beam pulses.

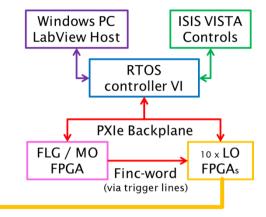

Local Oscillator

Implemented using LabView FPGA on NI PXIe7966R FPGA module (Virtex-5 SX95T FPGA /512 MB DRAM) + NI5782 250MS/s IF transceiver adapter module (6 x 1RF modules + 4 x 2RF Modules)

LO PID control loops

- Amplitude & Phase control on cavity using PID control loops for both I & Q vectors (10KHz Loop Response required)
- Will extend to Cavity tuning loop in the future (and have investigated use of reference signal to replace grid volts)

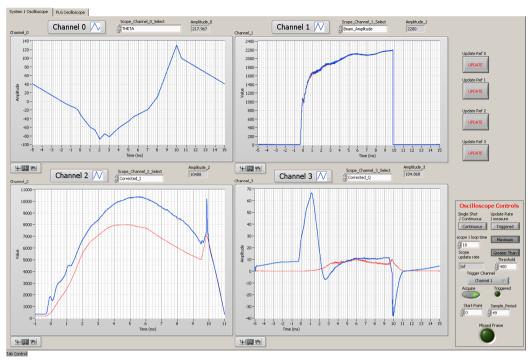

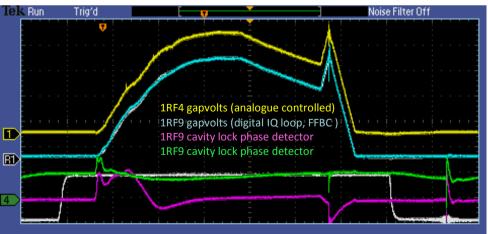

1st iteration I/Q ->CORDIC ->Amp/Phase loop

Now only as diagnostic

IQ Control Loop - tests

February / March 2019: Ran 40Hz Beam with digitally closed IQ loop on 1x 1RF system with High intensity beam and losses comparable to operational levels

No FF Beam Compensation applied (not possible at this beam intensity with the analogue system!)

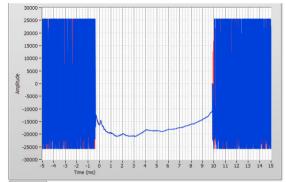

Apparent improved Loop performance over Amplitude / phase loops - remove need for FFBC?

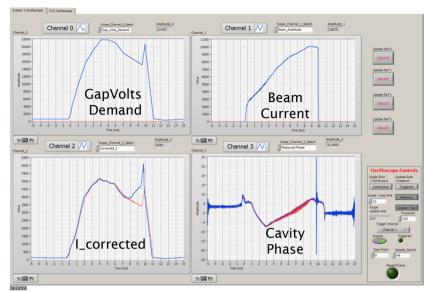

Without FFBC (or even with digital FFBC implemented in D-LPRF system if necessary) can retire old FFBC crates - source of high % of recent system outages

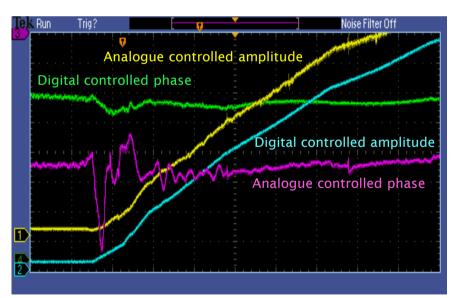

Digital FFBC - tests

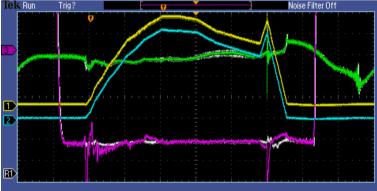

- 1. Set Beam IQ demod reference phase to match position of WCM
- 2. Adjust reference delay to give a reasonable beam phase from CORDIC

3. Adjust FFBC gain to match I_corrected to no beam case

Beam: 2.99e13 inj, 2.86e13 acc

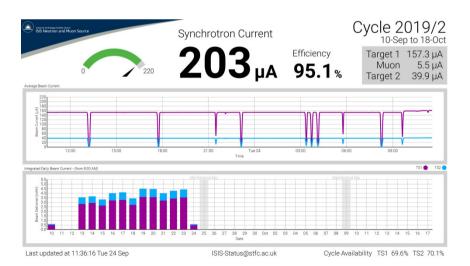

IQ Control Loop - Operation

Following success in the initial tests during machine development:

- Started the June ISIS user cycle running 1x1RF cavity with digital IQ loop control
- Had been running stably for ~1 week but
- ~3 hours into the User run, started to lose synchronisation between LO FPGAs
- Reverted to old FLG / MO FPGA and finished run in that state
- Subsequent investigations found differences in clock implementation on new 7971R FPGA module leading to additional 2.5ns delay Just sufficient to occasionally lose synch!
- Re-worked FLG/MO code to clock the F_{inc} bits at 20MHz (cf 40MHz previously)

ISIS User cycle 2019/2 (10th September - 25th October)

- Started cycle with 6x1RF cavities controlled with Digital IQ loops
- Problems with LINAC Tank 4 hampered beam setup Limited time to configure
- But running on analogue FFBC system
- Will change to digital FFBC (or no FFBC) for next cycle

D-LPRF: still to do!

New MQTT based controls interface

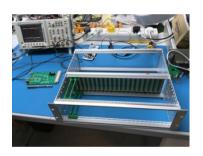

- Currently testing the code seems to work well
- Integrate LPRF On/Off controls into ISIS controls pages

Update FLG / MO FPGA code

- Provide external RF sweep / triggering to extract timing etc.
- Implement Beam phase and bunch length Loops digitally
 Also gives Beam I / Q to send to LOs via trigger lines if required

Complete analogue buffer crates

- Final Design nearing completion
- 3U Eurocard standard
- · Interface to NI front-end cards
- 24V High reliability Crate supply
- Implement IQ control of 2RF Cavities

Implement Cavity Tuning on LO FPGA

- Current utilisation ~ FLG: 50% cf LO: 90%
- May need more space: Implement FFBC IQ-demod on FLG / MO FPGA and broadcast over trigger lines

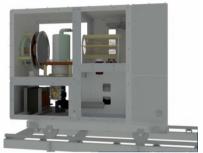

D-LLRF: the future

Investigate possible power saving

 GMS triggering Low or Zero Voltage RF demand for "no-beam" trigger (Trips / inhibits / downtime / shutdowns etc), and further reduce the RF electricity bill by 10-20%

New High Power Drive Amplifiers

- Update for different cavity loading
- Is FFBC necessary?
- Different Tuning Requirements?

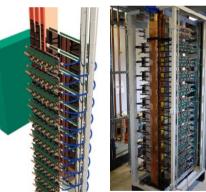

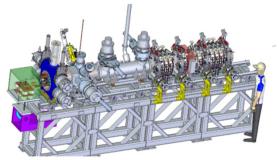

Starting to look at working on FETS D-LLRF

- uses same NI FlexRIO hardware
 - can re-use some of code eg Controls Interface, PI(D) loops
- FETS controls may run on EPICS? Can use this as a test bed for LabView / EPICS interface & then implement back into Synch D-LLRF
- Use above as a template for ISIS Pre-Injector upgrade LLRF

ISIS D-LLRF - Summary

ISIS LPRF not a greenfield site

- Staged implementation must be easily "Undo-able"
- Code snippets tested during limited machine development time (eg IQ beam phase, D-FFBC)
- Initial basic operation overcame initial mistrust of PXI platform from machine operators

Off the shelf hardware sped up initial development time

But needed hefty code workarounds for backplane latency, synch issues etc.

IQ operation

- IQ loop out-performs previous Amplitude/Phase loops with beam
 For ~2.5e13 protons old analogue system would lose phase lock and lose the beam!
- · Digital FFBC even if required will still enable ageing analogue units to retire

Lots of re-usable code modules for other LPRF projects

Running the Current User Cycle with 6x1RF controlled with digital IQ loops

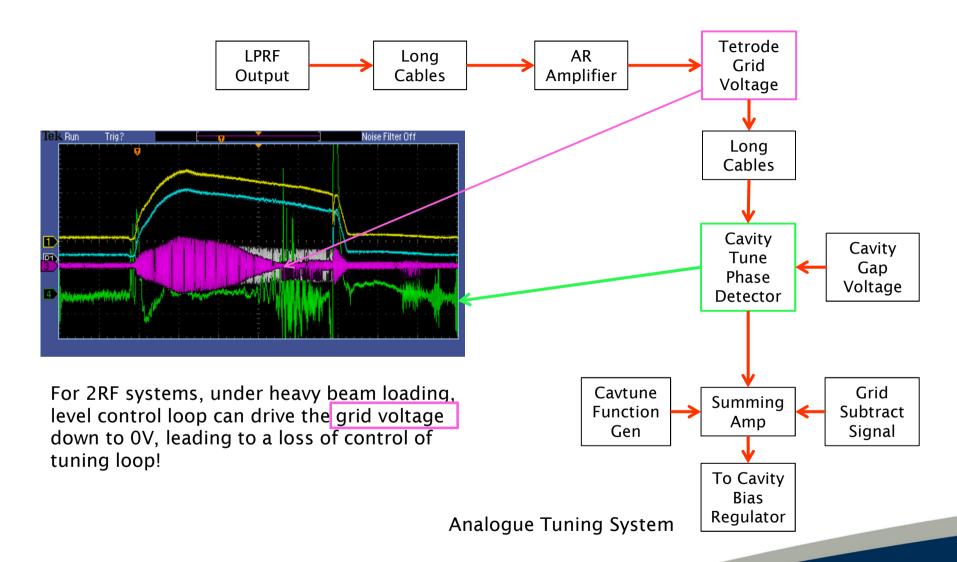

Soon Full Digital Control all 10 cavities!

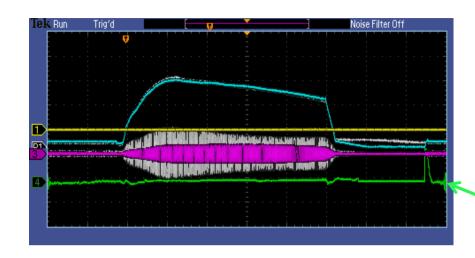

Thank you!

LLRF Cavity Tuning

LLRF Cavity Tuning

Implemented on 2RF Analogue System - Successfully operating over last 2 years

Recent operational tests implemented digitally on 1RF9 - equally successful

Operation for 6x1RF cavities delayed by start-up Tank 4 problems – but should set up for next cycle
